Git Client

Services Workbench allows you to use handle git files from the script itself. This is useful for file complex manager or using it during scenario execution as repository system is not available during the scenario execution.

In order to create an Git Client from Services Workbench, first you need to create a client providing 4 required parameters, username, password, the remote repository URL and the local directory. Directories are recommended to have the “{ds}” to make them relative to the current working file.

The client will create the folder during the git client creation, and if the file is there but also an empty folder it is ok.

Keep in mid if a file exists or if the folder is empty, creating the git file creation will fail

```
gitClient = createGitClient($username,$password,$url,"{ds}/localpath"[,$branch])
writeCSV("{ds}/localpath/data.csv",$csv_data)
gitClient.add(".");//Adding the file data.csv and other files
gitClient.commit("Message");//Commits message
gitClient.push();//Push but could fail if the branch is not updated
```
